Abstract: It is important to design an intelligent fire detection system based on the nervous system and particle optimization to find the fire time in the building. The use of intelligent methods in the fire detection system for data processing can reduce the risk of fire. In this paper, the original information of the firefighter network (FFN) is processed intelligently according to the possibility of the nervous system and the fire. In order to improve the quality of the system, the sensor data is applied to the generalized singular-value decomposition technique by analyzing the sound waves in the data. At the same time, the proposed neurological system was used for cell quality implantation new model particle mass optimization (PMO) using sushisen algorithms. In the simulation work, the data sensor is stored in the room by the network and is suitable for the target network. After that, compare the product to the traditional Multilayer Perceptron network. The simulation results represent a classic result.

Keywords: Firefighter Network, Neural Network, Particle Mass Optimization.

I. INTRODUCTION

Every year, huge fires impose irreparable damages all over the world. With the development of urban areas and increasing the numbers of skyscrapers in large cities there is an essential need, more than ever, for an applicable method to determine and extinguish fire in a timely manner. The development of technology has led researchers to employ new methods to reduce the risk of fire happening in urban areas as far as possible. The main features of fire alarm systems[1] are believed to be their high-speed response and their reliability.

The fire usually begins with a chemical and physical transformation associated with the emission of light, heat, smoke and flame[2]. The fire development[3] can be described as being comprised of four stages: incipient stage, smolder, developed, and decay period. Thus, the fire parameters can be defined as smog particle, heat or ambient temperature, the density of gas CO, and flame. These fire parameters are critical in fire detection, and intelligent fire detection systems[4] usually benefit from these parameters in detecting fire. Intelligent fire detection systems are able to learn and adapt to the situation and these capabilities are heavily dependent on environment. Many researches have been

made so far to achieve intelligent systems with minimal mis warning and delay-warning. Applying data-driven intelligent techniques are quite extensive among researchers.

So far, various methods have been suggested for determining an optimized fire detection system[5] including Bayesian inference, classical reasoning, fuzzy neural network and so on. Among these methods, using artificial neural networks has been always advantageous and in the center of attention. Neural networks are highly capable of overcoming the complexity of the system[6]. In order to use neural networks in fire detection systems, firstly, the data is collected from the sensors within the embedded sensor network and then they are given to the network as training data[7]. Finally, the data is used to train the network in ambient conditions. In case of fire risk, the trained network is able to promptly predict the likelihood of fire.

Conventional methods have been typically employed to train the neural networks. These methods are almost incapable of minimizing the network error[8]. Therefore, in this paper, an effective firefighter testing network[9] optimization method namely new model particle mass optimization (PMO) is used to efficiently

train the network and improve the system efficiency. Furthermore, a pre-processing step is performed on the raw output data of sensor network since the raw output data of sensor network is usually associated with noise which is detrimental to the system. Hence, the wavelet decomposition and generalized singular-value decomposition [10] are utilized to solve this problem. In order to gauge the effectiveness of the proposed method, the network is applied on data collected from a room in different conditions.

II. PRE-PROCESSING

In this section, firstly, the analysis of wavelet decomposition is presented and then generalized singular-value decomposition technique is used to eliminate non-essential principals of data, also known as high frequency principals.

2.1. Wavelet decomposition

Wavelets are a family of basic functions that exhibit localized properties both in time and frequency domains and can be presented as

$$\psi_{a,b}(x) = a^{1/2} \psi\left(\frac{x-b}{a}\right) \quad (1)$$

where a and b represent the dialation and translation, respectively, and are usually displayed as a pair in the normalized form, as below

$$\psi_{m,k}(x) = 2^{-m/2} \psi(2^{-m}t - k) \quad (2)$$

Each signal can be decomposed as a weighted sum of discretized orthogonal functions based on the participation of each level, as follows

$$x(t) = \sum_{m=1}^L \sum_{k=1}^N d_{mk} \psi_{mk}(t) + \sum_{k=1}^N a_{LK} \phi_{LK}(t) \quad (3)$$

where x is a signal in the time domain and d_{mk} represents wavelet coefficient or detail coefficient at the level n and position k . a_{LK} defines the coefficients of scaling function ϕ_{LK} , at the lowest level L and position k ;

One of the beneficial features of wavelets is their capability in decomposition of signals at different scales and in an orthogonal form. Therefore, in decomposition of wavelet, high scale principals and high frequency principals or noise are alike. The Generalized Singular Value decomposition method is exploited for the elimination of high scale principals and reconstruction of signals from the main principals of signals.

Consider $C_{M \times N}$ as the matrix of wavelet coefficients. Thus, according to the generalized singular value decomposition method, it becomes:

$$C_{M \times N} = \sum_{i=1}^N \sigma_i u_i v_i^T \quad (4)$$

where $\sigma_i = \sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_N \geq 0$, $u_i = [u_{1i}, u_{2i}, \dots, u_{Mi}]^T$ and $v_i = [v_{1i}, v_{2i}, \dots, v_{Ni}]^T$ are singular values of C , left singular vectors and right singular vectors, respectively, and $i = 1, 2, \dots, N$.

At this step some of the coefficients related to noise are eliminated and the de noising operation is completed by remodeling these coefficients. By taking P as the rank of data matrix without noise and C as the data matrix reduced by generalized singular-value decomposition the resulting matrix after noise elimination can be expressed as

$$\tilde{C} = \sum_{i=1}^P \tilde{\sigma}_i u_i v_i^T \quad (5)$$

where $\tilde{\sigma}_i$ represents the matrix of singular values after making singular values of $i > p$ equal to zero. A fine estimation of the rank of input data matrix results in the isolation of noise to a great extent without losing the main correct signal. In the next section, the network trained by PMO is introduced.

III. MULTI-LAYER FEED-FORWARD PERCEPTION

The Multilayer Perceptron network creates a non-linear mapping between input and output vectors by applying a multi-layer neural network. Figure (1) illustrates a multi-layer Multilayer Perceptron network.

Figure 1: Schematic view of the MLP network

where x_i , $i = 1, 2, \dots, n$ is the input data, w_{ij}^k , $j = 1, 2, \dots, m$ represents the network weight which is adjusted during the training. n , m are the input number and hidden node number, respectively. $k = 1, 2, \dots, K$ is the number of hidden layer.

In this network, different layers are connected by means of their weights. When the network is in the training phase, the weights are set based on the difference between the desired output and the network output and by using different sushisen algorithms.

One of the conventional methods to set the weights of network is the Steepest descend. This method is generally time-consuming due to the complexity of network and incapable of setting the weight to minimize the network error [15]. To solve this problem, evolution methods can be effective. One of the mostly used evolution methods is PMO. The PMO method has been extensively used in many researches. Read on references (17, 18, 19, 20) for further study. The combination of PMO method and Multilayer Perceptron network and the adaptation of network weights to the PMO optimization process are discussed in the following section.

3.1. Adaption to network training

In this work, a three-layer Multilayer Perceptron network is used. W_1 and W_2 represent the weight matrix between the input and hidden layer and between the hidden and output layer, respectively. Therefore, the weights are shown as particles in the PMO algorithm, and written as

$$W^i = \{W_1^i, W_2^i\} \quad (6)$$

Consequently, the position of each particle is given by

$$P^i = \{P_1^i, P_2^i\} \quad (6)$$

and P_b^i is the best member of the population and the velocity of particle i is denoted by V_j^i .

Thus, the velocity formula in PMO method can be calculated by the following equation:

$$V_{j,new}^i = V_{j,old}^i + \{v\alpha[P_j^i - W_j^i] + s\beta[P_{jb}^i - W_j^i]\}/t$$

$$W_{j,new}^i = W_{j,old}^i + V_j^i \quad (7)$$

where s , v , and $j=1,2$ are positive constants, α and β are random numbers between 0 and 1, and t is the time step and often equals to 1. The fitness function for the particle j in the form of output mean squared error is defined as

$$f(W_j) = 1/s \sum_{k=1}^s \left[\sum_{l=1}^o (t_{kl} - P_{kl} W_j^2)^2 \right] \quad (8)$$

where f characterizes the fitness function, t_{kl} is the target output, P_{kl} is the estimated output by the aforementioned network and based on weights W , s is the number of training samples and o is the number of neurons in the output layer. Figure (2) represents a schematic view of the fire detection intelligent network.

ΔT	Time difference
D	Actual distance
ea	Total absolute error of three-dimensional scenario
Ea	Average absolute error
Er	Average relative error
ex,y	Absolute error in x-y plane
ez	Absolute error of the z-axis
g	Gravity component
q	Quaternion
Ts	Time when velocity and acceleration are both zero (0)
Zr	Average absolute error of the z-axis
ω	Vector
xi	Distance from start point (0, 0) to point (xe,ye)

IV. SIMULATION

The output data of sensor network is collected and denoted as $X_{m \times n}$ in which m indicates the number of collected samples and n is the output BUS of the sensor network. In this simulation, the number of m=14980 and n=4 samples are collected using the sampling frequency of 0.1 Hz inside the room with various environmental conditions. Then the data set is

normalized. In the pre-processing section, the Mexican hat wavelet with the scale of V=3 is utilized. Meanwhile, the pre-defined threshold for the removal of non-essential principals is considered to be $\sigma_{threshold} = \%3$. This means the data contains %97 of information of the primary data after pre-processing step. Figure (3) shows the resulted signals before and after pre-processing.

Figure 3: A window plot of normalized sensor network data for (a). Noisy data and (b). Denoised data

In the next step, the data enters PMO-NN network for training. The parameters used for the network training are given in Table 1. The results of network training are

Table 1: Proposed system parameters

NO. OF NODES	PACKET DELIVERY RATIO		THROUGHPUT	
	AODV	DSDV	AODV	DSDV
10	1	0.904966	0.006668	0.006034
30	0.980403	0.79651	0.006536	0.005311
40	1	0.826577	0.006668	0.005512
50	1	0.914631	0.006667	0.006099
60	1	0.840805	0.006668	0.005607
70	0.999732	0.913557	0.006665	0.006092
80	0.980403	0.914094	0.006536	0.006095
90	1	0.914899	0.006668	0.006101
100	1	0.917584	0.006668	0.006118

shown in Figure (4).

Parameter Name		Value
Population Number		200
Max. Iteration		50
Epoch Number		20
Max. Error		1e-5
Population	initial value	rand(-10 10)

As these figures indicate, the training and testing results are also drawn by steepest descent in order to compare the proposed method and the conventional Multilayer Perceptron. The results show that the new method is well able to predict the likelihood of fire with less error than the Multilayer Perceptron.

Figure 4: Performance comparison of the proposed method PSO-NN and MLP network for train and test

In order to measure the effects of pre-processing on the output of the proposed network, another simulation is conducted in which the PMO-Multilayer Perceptron input data is employed in both noised and denoised conditions. Figure (5) illustrates the output of the two different conditions. Here also, the RMS error resulted from applying pre-processed data in both training and testing modes is lower than that in the condition without pre-processing.

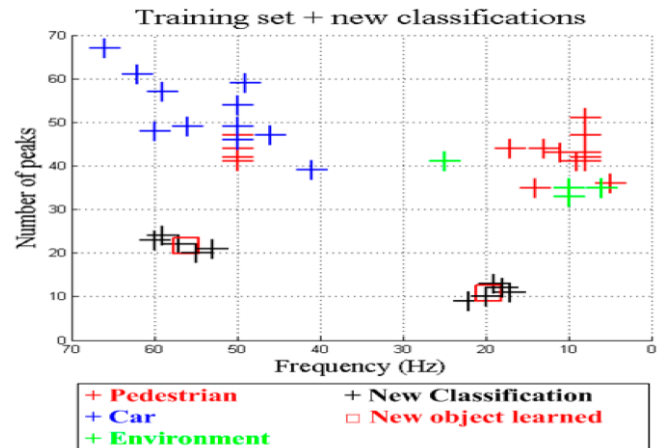

Figure 5: Performance comparison for training and testing PSO-NN for pre-processed and noisy data

It can be concluded that the noise in the data results in poor-training of network and consequently inaccurate output in testing.

SYSTEM DESCRIPTION: The experimental study has been conducted on a ASUS-X550C laptop with an Intel Core i3-3217U, 1.8 GHz CPU and with the RAM of 4GB, running in Windows 10. All programs are coded in MATLAB

Comparison on study

V. CONCLUSION

In-time detection of fire is one of the challenges of modern life. On the other hand, the fire detection systems are always sought to be at the highest efficiency and yet with the lowest price. Therefore, using an intelligent detection method seems inevitable. In this paper, an intelligent method based on neural network is employed for the effective detection of fire. In order to overcome the problems of conventional neural networks, a method is proposed which uses PMO optimization method for training the neural network. Applying this method results in lower error in neural network. Furthermore, the Multilayer Perception-PMO neural network is utilized which enables the omission of error by combining wavelet decomposition and Generalized Singular Value Decomposition technique. It is concluded that the proposed network results in increasing data SNR and network precision.
